

1 Rheology of disperse systems

N. Willenbacher and K. Georgieva

1.1 Introduction

Rheology of disperse systems is an extremely important processing parameter. Being able to characterize and manipulate the flow behavior of dispersions one can ensure their optimal performance. Automotive coatings, for example, should exhibit a distinct low-shear viscosity necessary to provide good leveling but to avoid sagging at the same time. Then a strong degree of shear thinning is needed in order to guarantee good pump- and sprayability. The rheological properties of dispersions, especially at high solid content, are complex and strongly dependent on the applied forces. Adding particles does not simply increase the viscosity of the liquid as a result of the hydrodynamic disturbance of the flow; it also can be a reason for deviation from the Newtonian behavior including shear rate dependent viscosity, elasticity and time dependent rheological behavior. Colloidal dispersions at moderate volume fraction normally flow like shear-thinning, low viscous liquids. At high concentrations dispersions often behave as solids and require a finite stress to deform the structural network and then start to flow. The microstructure deformed under stress usually can not recover immediately from large strains since the colloidal interactions governing the microstructure have a short range and decrease with increasing the interparticle separation. Depending whether the colloidal interactions are attractive or repulsive the particles can form different structures which determine the rheological behavior of the material. In the case of attractive particle interactions loose flocs with fractal structure can be formed immobilizing part of the continuous phase thus leading to larger effective particle volume fraction and correspondingly to increase of viscosity. Above a critical volume fraction a sample-spanning network forms, which results in a highly elastic, gel-like behavior and an apparent yield stress. Shear-induced breakup and recovery of floc structure leads to thixotropic behavior. Electrostatic or steric repulsion between particles define an excluded volume which is not accessible by another particle leading to crystalline or gel-like state at particle concentrations lower than the maximum packing fraction.

Characterization of the microstructure and flow properties of dispersions is essential for the understanding and controlling their rheological behavior. In this chapter we first introduce methods and techniques for standard rheological tests and then characterize the rheology of hard
