Simple Linear Regression

the statistical approach for a quantitative outcome and a single quantitative explanatory variable

9.1 The model behind linear regression

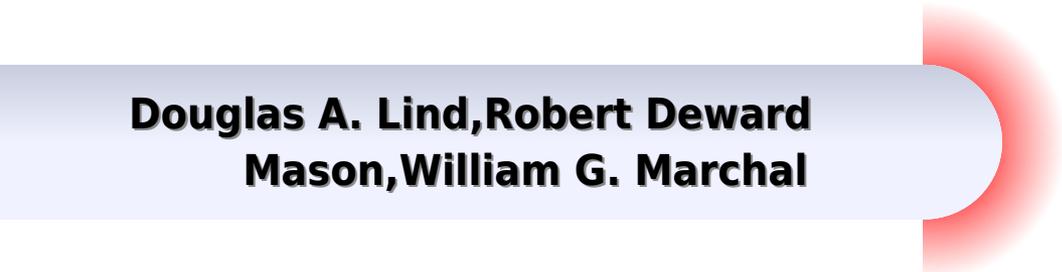

When we are measuring the relationship between a quantitative outcome and a single quantitative explanatory variable, simple linear regression is the most commonly considered analysis method. (The “weight” part tells us we are only considering a single explanatory variable.) In linear regression we usually have many different values of the explanatory variable, and we usually observe their values between the observed values of the explanatory variable are also possible values of the explanatory variable. We postulate a linear relationship between the population mean of the outcome and the value of the explanatory variable. If we let Y be some outcome, and X be some explanatory variable, then we can express the structural model using the equation

$$E(Y|x) = \beta_0 + \beta_1 x$$

where $E(Y)$, which is read “expected value of”, indicates a population mean; $E(Y)$, which is read “ Y given x ”, indicates that we are looking at the possible values of Y when x is restricted to some single value; β_0 , read “beta zero”, is the intercept parameter; and β_1 , read “beta one”, is the slope parameter. β represents both the two parameters or parameter estimates used in the equation for predicting Y from
