Drawing The Solar System To Scale

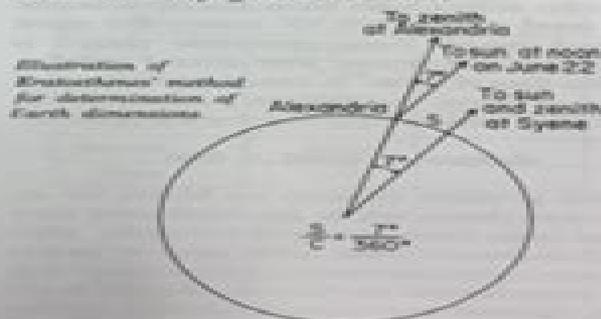

The earliest observers of the heavens were unable, and perhaps uninterested, in determining the distances to celestial objects. Their observations primarily dealt with the periodic nature of celestial motions such as the changing phases of the moon, rising and setting of the sun, and seasonal changes. The Greek astronomers, however, were far more ambitious in studying the heavens, and over hundreds of years applied geometry and other mathematical innovations to obtain knowledge about solar system distances and relative sizes of the sun, Earth and moon.

Today, we have detailed knowledge of the orbital distances and the sizes of the planets. This knowledge comes from the efforts of a long line of scientists beginning with the Greek astronomers. One of the first steps was the conclusion that the earth and moon are spherical objects. The moon's shape was deduced from the fact that as the moon goes through its cycle of phases, the terminator shows a curved shape at all phases except the quarter and full moon. Together with its overall round shape, the observations implied a spherical moon. Determining the shape of the Earth is more complicated because we live on the Earth, and can't see it as we see the moon. Some Earth-bound observations, however, suggest the Earth's spherical shape. These observations include the round shape of the Earth's shadow cast on the moon during eclipses, and the changing position of stars as a traveler moves north or south.

The first recorded attempts at "measuring" the size and distance of the sun, moon and Earth, are those of Aristarchus of Samos (ca. 270 B.C.). Aristarchus used geometry to measure the sun-earth distance in terms of the moon-Earth distance. He applied the geometrical analysis to the moon's orbit by observing the time interval between the first and third quarter phase of the moon. Using these measurements, he went on to estimate the relative Earth-sun-moon diameters by analyzing apparent sizes of the sun, moon and

Earth shadow during lunar eclipses. Although his results were very inaccurate, his attempt was important because it marked an objective and logical approach to studying celestial objects. About 100 years later, Hipparchus using the correct angular size of the sun and moon, was able to determine the relative diameters more accurately.

Another significant Greek astronomer, Eratosthenes (ca. 200 B.C.), was able to measure the size of the Earth by some simple observations and an application of simple geometry. The diagram below illustrates the geometry required for this measurement. When the sun is overhead, at one point on the Earth's surface, it will **not** be overhead for an observer north or south of that location. The angular difference between the observed position of the sun, together with knowledge of the distance between these two observers, can be translated into the circumference (C) of the earth. Greek mathematicians had long ago shown there is a simple relationship between the circumference of a circle and its diameter, $C = \pi D$. Thus Eratosthenes knew the size of the Earth, and its spherical shape in 200 B.C., long before Columbus' voyage of 1492 A.D.
