## *Introduction*

Any large information source (data base) can be thought of as a table (with multiple fields), containing information.

For example:

A telephone book has fields *name*, *address* and *phone number*. When you want to find somebody's phone number, you search the book based on the *name* field.

A user account on AA-Design, has the fields *user\_id*, *password* and *home folder*. You log on using your *user\_id* and *password* and it takes you to your *home folder*.

To find an entry (field of information) in the table, you only have to use the contents of **one** of the fields (say *name* in the case of the telephone book). You **don't** have to know the contents of all the fields. The field you use to find the contents of the other fields is called the **key**.

Ideally, the key should uniquely identify the entry, i.e. if the key is the *name* then no two entries in the telephone book have the same name.

We can treat the Table formulation as an abstract data type. As with all ADT's we can define a set of operations on a table

<b>Operation</b>	<b>Description</b>
Initialize	Initialize internal structure; create an empty table
IsEmpty	True iff the table has no elements
Insert	Given a key and an entry, insert it into the table
Find	Given a key, find the entry associated with the key
Remove	Given a key, find the entry associated with the key and remove it from the table
