Photonic Integrated Circuit (PIC) Device Structures: Background, Fabrication Ecosystem, Relevance to Space Systems Applications, and Discussion of Reliability

National Aeronautics and Space Administration, 2019-01-14

Electronic integrated circuits are considered one of the most significant technological advances of the 20th century with demonstrated impact in their ability to incorporate successively higher numbers of transistors and construct electronic devices onto a single CMOS chip. Photonic integrated circuits (PICs) exist as the optical analog to integrated circuits; however, in place of transistors, PICs consist of numerous scaled optical components including such building block structures as waveguides, multimode interference (MMI) devices, lasers, and optical ring resonators. The ability to construct electronic and photonic components on a single microsystems platform offers transformative potential for the development of technologies in fields including communications, biomedical device development, autonomous navigation, and chemical and atmospheric sensing. Developing on-chip systems that provide new avenues for integration and replacement of bulk optical and electro-optic components also reduces size, weight, power, and cost (SWaP-C) limitations, which are important in the selection of instrumentation for specific flight projects. The number of applications currently emerging for complex photonics systems, particularly in data communications, warrants additional investigations when considering reliability for space systems development. This Body of Knowledge document seeks to provide an overview of existing integrated photonics architectures, the current state of design, development, and fabrication ecosystems in the United States and Europe, and potential space applications with emphasis given to associated radiation effects and reliability.
