

Fog Orchestration for Internet of Things Services

Large-scale Internet of Things (IoT) services such as healthcare, smart cities, and marine monitoring are pervasive in cyber-physical environments. These complex IoT services are increasingly composed of sensors, devices, and compute resources within fog computing infrastructures. Orchestrating such applications can simplify maintenance and enhance data security and system reliability. However, efficiently dealing with these services' dynamic variations and transient operational behavior is a crucial challenge. This article provides an overview of the core issues, challenges, and future research directions in fog-enabled orchestration for IoT services.

Cyber-physical environments encompass physical and virtual components capable of interfacing and interacting with existing network infrastructure, enabling novel applications in areas such as smart cities, intelligent transportation, and autonomous vehicles. The explosive growth in data generation has led to a focus in both research and industry on issues related to effectively extracting insights from such data to assist in the design of cyber-physical systems. Internet of Things (IoT) services typically comprise a set of software components running in different locations and connected through dynamic networks (such as 4G, wireless LAN, and the Internet). Systems such as data centers and wireless sensor networks (WSNs) underpin the data storage and compute resources required for operating these components.

Fog computing extends cloud computing by moving computation and data

storage to the edge of the network, allowing for reduced latency and response delay jitter for applications.^{1,2} These characteristics are particularly important for latency-sensitive applications, such as gaming and video streaming. In the IoT environment, existing applications and physical devices can be leveraged as fundamental appliances and composed in a mashup style to control development cost and maintenance pressure. Orchestration is a key concept within distributed systems, enabling the alignment of deployed applications with users' business interests. We propose a fog orchestrator, to provide the centralized arrangement of the resource pool, mapping applications with specific requests and providing an automated workflow to physical resources (deployment and scheduling); workload execution management with runtime quality of service (QoS) control; and time-efficient directive generation to manipulate specific objects.

Orchestration of Distributed Ingestion and Processing of IoT Data for Fog Platforms Juan Luis Pérez Rico, 2018 In recent years there has been an extraordinary growth of the Internet of Things IoT and its protocols The increasing diffusion of electronic devices with identification computing and communication capabilities is laying ground for the emergence of a highly distributed service and networking environment The above mentioned situation implies that there is an increasing demand for advanced IoT data management and processing platforms Such platforms require support for multiple protocols at the edge for extended connectivity with the objects but also need to exhibit uniform internal data organization and advanced data

processing capabilities to fulfill the demands of the application and services that consume IoT data. One of the initial approaches to address this demand is the integration between IoT and the Cloud computing paradigm. There are many benefits of integrating IoT with Cloud computing. The IoT generates massive amounts of data and Cloud computing provides a pathway for that data to travel to its destination. But today's Cloud computing models do not quite fit for the volume, variety, and velocity of data that the IoT generates. Among the new technologies emerging around the Internet of Things to provide a new whole scenario, the Fog Computing paradigm has become the most relevant. Fog computing was introduced a few years ago in response to challenges posed by many IoT applications, including requirements such as very low latency, real-time operation, large geo-distribution, and mobility. Also, this low-latency, geo-distributed, and mobility environment is covered by the network architecture MEC (Mobile Edge Computing) that provides an IT service environment and Cloud computing capabilities at the edge of the mobile network within the Radio Access Network (RAN) and in close proximity to mobile subscribers. Fog computing addresses use cases with requirements far beyond Cloud-only solution capabilities. The interplay between Cloud and Fog computing is crucial for the evolution of the so-called IoT, but the reach and specification of such interplay is an open problem. This thesis aims to find the right techniques and design decisions to build a scalable distributed system for the IoT under the Fog Computing paradigm to ingest and process data. The final goal is to explore the trade-offs and challenges in the design of a solution from Edge to Cloud to address opportunities that current and future technologies will bring in an integrated way. This thesis describes an architectural approach that addresses some of the technical challenges behind the convergence between IoT, Cloud, and Fog, with special focus on bridging the gap between Cloud and Fog. To that end, new models and techniques are introduced in order to explore solutions for IoT environments. This thesis contributes to the architectural proposals for IoT ingestion and data processing by 1) proposing the characterization of a platform for hosting IoT workloads in the Cloud, providing multi-tenant data stream processing capabilities, the interfaces over an advanced data-centric technology, including the building of a state-of-the-art infrastructure to evaluate the performance and to validate the proposed solution; 2) studying an architectural approach following the Fog paradigm that addresses some of the technical challenges found in the first contribution. The idea is to study an extension of the model that addresses some of the central challenges behind the convergence of Fog and IoT; 3) Design a distributed and scalable platform to perform IoT operations in a moving data environment. The idea after studying data processing in Cloud and after studying the convenience of the Fog paradigm to solve the IoT close to the Edge challenges is to define the protocols, the interfaces, and the data management to solve the ingestion and processing of data in a distributed and orchestrated manner for the Fog Computing paradigm for IoT in a moving data environment.
