Abstract

This paper investigates the comparability of several multi-layered, woven filter media using air, water and bubble point methods. Estimated filter efficiencies from the bubble point measurements were then compared to a new sonic challenge test method where precision micropheres are flushed through the pores. Inconsistencies in the bubble point filter efficiencies were found to be dependent on the openness or permeability of the weave. The filter efficiency of a non-woven metal filter medium was then related to the pore size distribution measured by microscopy.

Key words: Permeability, woven filter media, metal filter media

1. Introduction

In order to permit clean filter through materials the pore structure is clearly defined as often viewed under a microscope an aperture can be observed with increased definition from the top and side. However, Figure 1(a), in most cases it is possible to measure across the opening in each direction to get an indication of the pore structure.

Microscopic aperture measurement is not possible however on composite or double-layered weave (DLW) structures similar to those in Figure 1 (b). When viewed from the top surface it is difficult to see through the fibres (unless it is extremely loose). In most cases the cross-sectional path through a composite or DLW is a tortuous one with interweaving between the layers. Furthermore, increasingly lighter weaves in the same weave class, become looser and the use of microscopy as an analytical tool to measure aperture size.

In complex, 3-dimensional filter media, permeability via capillary flow from wetted media has long been used for assessing the relative pore size distribution (RSDC). Theoretically it is based on the Laplace equation for cylindrical capillary pores (ASTM F-330-80 and (see ASTM)). However, most filter media have irregular pores, which makes the theoretical assumptions suspect and this is especially the case in multi-layered structures. Nevertheless, permeability has been firmly established as a low cost procedure for filter media characterisation, and now can even be successfully used to assess efficiency.

Many investigators used the standard bubble point method for RSDC determinations, but with the advent of the Coulter's permeometer in 1966 this task has become relatively easy. In the ensuing years many other permeometers have been introduced.

Using multi-layered woven media, as shown in Figure 1, this paper compares four methods of pore size analysis based on permeability testing. In addition it will compare permeability data with that of direct so-called 'Challenge test'. In this method standard test dusts or glass beads are presented to a filter medium and the particles in the downstream filtrate analysed.

In the least development of the method, accurately calibrated, narrow size distribution glass microspheres have been produced covering the size range 2 - 100µm in 20 grades. Knowing the size distribution by weight eliminates the need for particle sizing equipment as the pore size can be directly related to the percentage of the standard passing the filter medium through a calibration graph or formula.
