

8. Aggregate Planning Problem

A company wants a high-level, aggregate production plan for the next 6 months. Projected orders for the company's products are listed in Table 3. Over the 6-month period, units may be produced in one month and stored in inventory to meet demand at some later time. Because of seasonal factors, the cost of production is not constant, as shown in the table.

Table 3: Aggregate Planing Data

Month	Demand (units)	Production cost (\$/unit)
1	1300	100
2	1400	105
3	1000	110
4	800	115
5	1700	110
6	1900	110

The cost of holding an item in inventory is \$4 per unit per month. Items produced and sold in the same month are not placed in the inventory. The maximum number of units that can be stored is 250. The initial inventory level at the beginning of the planning horizon is 200 units; the final inventory level at the end of the planning horizon is to be 100 units. Construct a mathematical program that determines the optimal amount to produce in each month so that demand is met while minimizing total production cost and inventory holding cost. Shortages are not permitted.

ELSP surfaces from competition among products for a scarce resource usually machine time When scheduling production of batches in this environment two issues must be resolved the size of batches and the start times for production of each batch

Standard approaches to the ELSP focus on scheduling multiple products on a single machine This thesis addresses three important issues that put the scheduling problem in the context of its physical setting and range of parameters idle time the zero switch rule and stochastic input to a bottleneck machine In most scheduling heuristics the reason for idle time is to balance cyclic production patterns Idle time is also optimal in solutions to problems with high setup costs We show that the condition for inducing idle time given zero setup costs is when one product has dominant holding costs and the remaining products have low machine utilization A common policy in scheduling is to start production only after the inventory reaches zero This policy is called the zero switch rule ZSR and is regarded as a good scheduling policy We show that the condition when ZSR is not optimal is when the ZSR solution yields lumpy production patterns for a product with dominant holding costs
