ABSTRACT

We propose a new unsupervised learning technique for extracting information from large text collections. We model documents as if they were generated by a two-stage stochastic process. Each author is represented by a probability distribution over topics, and each topic is represented as a probability distribution over words for that topic. The words in a multi-author paper are assumed to be the result of a mixture of each authors' topic mixture. The topic-word and author-topic distributions are learned from data in an unsupervised manner using a Markov chain Monte Carlo algorithm. We apply the methodology to a large corpus of 160,000 abstracts and 85,000 authors from the well-known CiteSeer digital library, and learn a model with 300 topics. We discuss in detail the interpretation of the results discovered by the system including specific topic and author models, ranking of authors by topic and topics by author, significant trends in the computer science literature between 1990 and 2002, parsing of abstracts by topics and authors and detection of unusual papers by specific authors. An on-line query interface to the model is also discussed that allows interactive exploration of author-topic models for corpora such as CiteSeer.

1. INTRODUCTION

With the advent of the Web and various specialized digital libraries, the automatic extraction of useful information from text has become an increasingly important research

area in data mining. In this paper we discuss a new algorithm that extracts both the topics expressed in large text document collections and models how the authors of documents use those topics. The methodology is illustrated using a sample of 160,000 abstracts and 80,000 authors from the well-known CiteSeer digital library of computer science research papers (Lawrence, Giles, and Bollacker, 1999). The algorithm uses a probabilistic model that represents topics as probability distributions over words and documents as being composed of multiple topics. A novel feature of our model is the inclusion of author models, in which authors are modeled as probability distributions over topics. The author-topic models can be used to support a variety of interactive and exploratory queries on the set of documents and authors, including analysis of topic trends over time, finding the authors who are most likely to write on a given topic, and finding the most unusual paper written by a given author. Bayesian unsupervised learning is used to fit the model to a document collection.

Supervised learning techniques for automated categorization of documents into known classes or topics has received considerable attention in recent years (e.g., Yang, 1998). For many document collections, however, neither predefined topics nor labeled documents may be available. Furthermore, there is considerable motivation to uncover hidden topic structure in large corpora, particularly in rapidly changing fields such as computer science and biology, where predefined topic categories may not accurately reflect rapidly evolving content.

Automatic extraction of topics from text, via unsupervised learning, has been addressed in prior work using a number of different approaches. One general approach is to represent the high-dimensional term vectors in a lower-dimensional space. Local regions in the lower-dimensional space can then be associated with specific topics. For example, the WEISSOM system (Lagus et al. 1999) uses non-linear dimensionality reduction via self-organizing maps to represent term vectors in a two-dimensional layout. Linear projection techniques, such as latent semantic indexing (LSI), are also widely used (Berry, Dumais, and O'Brien, 1995). For example, Deerwester et al. (1990), while not using the term "topics" per se, state:

Roughly speaking, these factors may be thought of as artificial concepts; they represent extracted common meaning components of many different
