

8-2 Photosynthesis: An Overview

The key cellular process identified with energy production is photosynthesis. In the process of **photosynthesis**, plants use the energy of sunlight to convert water and carbon dioxide into high-energy carbohydrates - sugars and starches - and oxygen, a waste product.

The Photosynthesis Equation

Because photosynthesis usually produces glucose (C₆H₁₂O₆) as the final product, the overall equation for photosynthesis can be shown as follows:

Photosynthesis uses the energy of sunlight to convert water and carbon dioxide into high-energy sugars and oxygen. Plants then use the sugars to produce complex carbohydrates such as starches. Plants obtain carbon dioxide from the air or water in which they grow.

Light and Pigments

Although the equation tells you that water and carbon dioxide are required for photosynthesis, it does not tell you how plants use these low-energy raw materials to produce high-energy sugars. To answer that question, you have to know how plants capture the energy of sunlight. **In addition to water and carbon dioxide, photosynthesis requires light and chlorophyll, a molecule in chloroplasts.**

Energy from the sun travels to Earth in the form of light. Sunlight, which your eyes perceive as "white" light, is actually a mixture of different wavelengths of light. Many of these wavelengths are visible to your eyes and make up what is known as the visible spectrum. Your eyes see the different wavelengths of the visible spectrum as different colors.

Plants gather the sun's energy with light-absorbing molecules called **pigments**. The plants' principal pigment is **chlorophyll**. There are two main types of chlorophyll: chlorophyll *a* and chlorophyll *b*.

Chlorophyll absorbs light very well in the blue-violet and red regions of the visible spectrum. However, chlorophyll does not absorb light well in the green region of the spectrum.
